SPEAKING SCRIPT

Database - cost layers and profit history

Ampaabeng Raymond Kyeremeh

Database management and maintenance

Duration	about 1 minute 45 seconds
Slot in the video	Closes the video (after Francis)
On camera	Screen share of migration 007 and 008, then a product with two layers

How to use this script

Read the spoken words naturally. Do not read lines in [SQUARE BRACKETS]; those are camera or screen cues. If you run long, skip a paragraph marked OPTIONAL. Aim for the duration on the cover. The full team video should land between 8 and 15 minutes.

The problem we solved last

[FACE, then SHOW: 007 and 008 SQL files.]

I am Raymond. I work on the database with Francis. Here is the shop problem in one sentence. They buy a carton of books at two cedis fifty, then restock later at four cedis, then they raise the selling price. If we only store one cost on the product, analytics will lie: leftover old books look as expensive as the new ones.

What we store

Migration 007 added cost price on the product and unit cost on each sale line. That protected completed sales. Migration 008 added product stock layers: each restock is a lot with its own cost, a snapshot of the listed price, and quantity remaining. The product row still has the current shelf price and the cost we expect to pay next. Layers are the truth of what is on the shelf.

When they sell, we consume oldest remaining quantity first. The sale stamps today's selling price and that lot's cost. Old stock, new stock, honest profit. Seed and backup know about layers, so a restore does not flatten the shop's history.

[WIDE SHOT OF THE TEAM if you can. Smile. Do not rush this last paragraph.]

So that is Regimens. A shop that used a notebook now has a web app: designed for the counter, built in React, served by a secure API, and stored in Postgres with a memory for what stock actually cost. We are Team Regimens. Thank you.
